

Attendance:

- Angela Lojko
- Thomas Webber
- Oli Kosiacki

Ethical considerations:

- Recipes might be inaccurately presented or lack cultural context
 - Resolution: provide historical context for dishes, verify sources, allow community feedback on dishes
- Users altering the dish may lose its cultural significance, so having a snippet explaining why the ingredients are used and

Data Source & Backend Integration

- **Data Source**
 - Will pull from the recipes api, map api, possibly web scraping

Choice & Fit of Data Structures

- **Tries: (search bar)**
 - **Autocompletes off of the weights**
 - The more users search a dish, the weight goes up (initial weights 0)
 - First search recommendations will be user history
- **Either these three:**
 - **Priority Queue (Dish Carousel)**
 - **Pagination**
 - **Display top K popular dishes that are stored as nodes that have the dish name plus it's picture**
 - **The more users click on a dish, the weight goes up (initial weights researched and added)**
 - **Display bottom K popular dishes**

-
- Splay Trees (Not chosen)
 - Most frequently accessed dishes are at the top, making future accesses faster with no explicit balancing
 - One page of the web app can display leaf nodes which have the least popular dishes
 - User unpredictability could lead to bad time efficiency as looking up obscure/unpopular recipes brings those recipe nodes to the top
 - Looking up leaf nodes to show least popular dishes has a bad time efficiency $O(n)$
- B-Trees (not chosen?)
 - Pagination
 - Could have been used as SQL offsets for pagination
 - Unsorted, unordered data might be a problem — would have to combine some other data structure, thus increasing run-time

Potential dish tags:

- Location (where it originated from)
- Ingredients
- Serving style?
- Meal time (time of day most commonly eaten)
- Course type (e.g. main course, dessert, side dish)
- Cooking method (e.g. boiled, fried, baked)
- Taste type?

Timeline:

- This week 03/09 — 03/14 —
 - plan the logistics (database, structures, visualization)
- Next week 03/15 — 03/22 —
 - Thomas will do research on Django
 - Oli will do research on React
 - Angela will do research on both (react and django)
- Spring Week 03/23 - 03/29 —
 - *Backend* – Thomas will start coding the back-end
 - *Frontend* – Oli will start working on the front end to implement a homepage that shows top k dishes
- 03/30 - 04/05 — **April 03rd rough draft due (one page routing)**
 - *Frontend* – Oli will aim to have front end with function input and output on the front end
 - *Backend* – Thomas will aim to have the data pulled in from the API and stored into the data structure
- 04/06 - 04/12 —
 - *Frontend* – Oli will focus on making dishes on the main page reroute to each recipes individual page where recipe and cultural significance is shown
 - *Backend* – Thomas will pull in the data for the cultural history regarding the dishes
- 04/13 - 04/26 – **April 22nd polished draft**
 - *Frontend* – aim to have multiple page routing and connected to back end
 - *Backend* – have data completely pulled in completely; all recipes will have external data stored in our internal database
- **Project completion for April 27th**
- Practice April 28th for presentation
